1.10.1 平面耐蚀性 corrosion resistance of flat sections

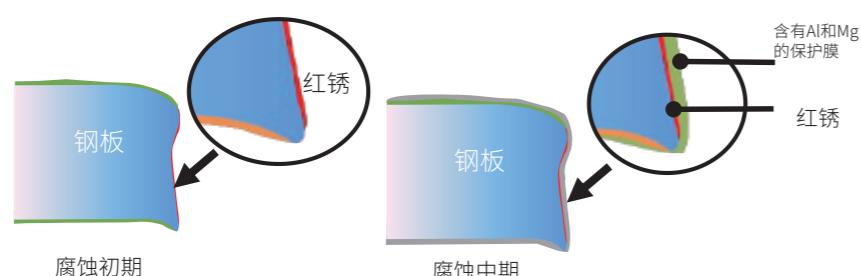

与纯锌 (GI) 镀层相比, 由于锌铝镁镀层中所含的铝 (Al) 和镁 (Mg) 作用, 随着时间推移, 在镀层表面形成附着性强的保护膜, 抑制镀层的腐蚀, 从而发挥优异的耐蚀性。热浸镀锌虽然也在镀层表面形成保护膜, 但是该保护膜表面粗糙且附着性低, 故腐蚀因子容易穿透, 造成镀层腐蚀扩大。

Compared with pure zinc (GI) coating, a protective film with strong adhesion is formed on the coating surface over time due to the action of Al and Mg contained in Zn-Al-Mg coating. The protective film with strong corrosion resistance can inhibit the corrosion of the coating, so as to give play to excellent corrosion resistance. Although hot-dip zinc coating also forms a protective film on the surface, the surface of the protective film is rough and possesses low adhesion. As a consequence, the corrosion factor is easy to penetrate, resulting in the expansion of coating corrosion.

1.10.2 切口耐蚀性 corrosion resistance of cut edge

钢板的切口端面暴露的基体在空气中由于雨水等原因容易发生氧化生红锈。在切口断面部位, 从镀层析出的 Al、Mg 元素会在端口部位生成致密的锌系保护膜, 并覆盖断口部位, 从而发挥优异的耐蚀性。

The exposed cut edge of substrate is oxidized due to rain, condensation, etc. Excellent corrosion resistance is achieved on cut edge parts by covering the ends with a fine zinc-based protective film that contains Al and Mg leaching from the coating layer.
